Section 1: Coding

## 1. Problem Statement

Samantha is working on a text analysis tool that compares two words to find common and unique letters. She wants a program that reads two words, w1, and w2, and performs the following operations:

Print the letters common to both words, in alphabetical order. Print the letters that are unique to each word, in alphabetical order. Determine if the set of letters in the first word is a superset of the letters in the second word. Check if there are no common letters between the two words and print the result as a Boolean value.

Ensure the program ignores case differences and leading/trailing spaces in the input words.

Your task is to help Samantha in implementing the same.

# **Input Format**

The first line of input consists of a string representing the first word, w1.

The second line consists of a string representing the second word, w2.

## **Output Format**

The first line of output should display the sorted letters common to both words, printed as a list.

The second line should display the sorted letters that are unique to each word, printed as a list.

The third line should display a Boolean value indicating if the set of letters in w1 is a superset of the set of letters in w2.

The fourth line should display a Boolean value indicating if there are no common letters between w1 and w2.

Refer to the sample output for the formatting specifications.

# Sample Test Case

```
Input: program
Peace
Output: ['a', 'p']
['c', 'e', 'g', 'm', 'o', 'r']
False
False
```

#### Answer

```
# You are using Python
# Read input words, strip spaces and convert to lowercase
w1 = input().strip().lower()
w2 = input().strip().lower()

# Convert to sets of letters
set1 = set(w1)
set2 = set(w2)
```

```
# Letters common to both words, sorted alphabetically
   common_letters = sorted(set1.intersection(set2))
   # Letters unique to each word, sorted alphabetically
   unique_letters = sorted(set1.symmetric_difference(set2))
   # Check if set1 is superset of set2
   is_superset = set1.issuperset(set2)
   # Check if no common letters exist
   no_common = len(set1.intersection(set2)) == 0
   # Print results
   print(common_letters)
   print(unique_letters)
print(is_superset)
   print(no_common)
```

Status: Correct Marks: 10/10

#### 2. Problem Statement

Emily is a librarian who keeps track of books borrowed and returned by her patrons. She maintains four sets of book IDs: the first set represents books borrowed, the second set represents books returned, the third set represents books added to the collection, and the fourth set represents books that are now missing. Emily wants to determine which books are still borrowed but not returned, as well as those that were added but are now missing. Finally, she needs to find all unique book IDs from both results.

Help Emily by writing a program that performs the following operations on four sets of integers:

Compute the difference between the borrowed books (first set) and the returned books (second set). Compute the difference between the added books (third set) and the missing books (fourth set). Find the union of the 24/50/055 results from the previous two steps, and sort the final result in descending order.

Input Format

The first line of input consists of a list of integers representing borrowed books.

The second line of input consists of a list of integers representing returned books.

The third line of input consists of a list of integers representing added books.

The fourth line of input consists of a list of integers representing missing books.

## **Output Format**

The first line of output displays the difference between sets P and Q, sorted in descending order.

The second line of output displays the difference between sets R and S, sorted in descending order.

The third line of output displays the union of the differences from the previous two steps, sorted in descending order.

Refer to the sample output for the formatting specifications.

## Sample Test Case

```
Input: 1 2 3
2 3 4
5 6 7
6 7 8
Output: [1]
[5]
```

#### Answer

```
# You are using Python
# Read the input sets from input lines
P = set(map(int, input().split()))
Q = set(map(int, input().split()))
R = set(map(int, input().split()))
S = set(map(int, input().split()))
```

# Compute differences

```
diff_PQ = sorted(P - Q, reverse=True)
diff_RS = sorted(R - S, reverse=True)

# Compute union of differences
union_diff = sorted(set(diff_PQ).union(diff_RS), reverse=True)

# Print the results as lists
print(diff_PQ)
print(diff_RS)
print(union_diff)
```

Status: Correct Marks: 10/10

# 3. Problem Statement

James is an engineer working on designing a new rocket propulsion system. He needs to solve a quadratic equation to determine the optimal launch trajectory. The equation is of the form ax2 +bx+c=0.

Your task is to help James find the roots of this quadratic equation. Depending on the discriminant, the roots might be real and distinct, real and equal, or complex. Implement a program to determine and display the roots of the equation based on the given coefficients.

## Input Format

The first line of input consists of an integer N, representing the number of coefficients.

The second line contains three space-separated integers a,b, and c representing the coefficients of the quadratic equation.

## **Output Format**

The output displays:

- 1. If the discriminant is positive, display the two real roots.
- 2. If the discriminant is zero, display the repeated real root.
- 3. If the discriminant is negative, display the complex roots as a tuple with real and imaginary parts.

Refer to the sample output for formatting specifications.

```
Sample Test Case
Input: 3
156
Output: (-2.0, -3.0)
Answer
# You are using Python
import math
N = int(input()) # Number of coefficients (should be 3)
a, b, c = map(int, input().split())
discriminant = b**2 - 4*a*c
if discriminant > 0:
   root1 = (-b + math.sqrt(discriminant)) / (2*a)
  root2 = (-b - math.sqrt(discriminant)) / (2*a)
   # print roots as a tuple
   print((root1, root2))
elif discriminant == 0:
   root = -b / (2*a)
  # print repeated root twice as a tuple
  print((root, root))
else:
   real = -b / (2*a)
  imag = math.sqrt(-discriminant) / (2*a)
  # print complex roots as tuple of tuples
   print(((real, imag), (real, -imag)))
```

Status: Correct Marks: 10/10

## 4. Problem Statement

Alex is tasked with managing the membership lists of several exclusive clubs. Each club has its own list of members, and Alex needs to determine the unique members who are part of exactly one club when considering all

clubs together.

Your goal is to help Alex by writing a program that calculates the symmetric difference of membership lists from multiple clubs and then finds the total number of unique members.

## **Input Format**

The first line of input consists of an integer k, representing the number of clubs.

The next k lines each contain a space-separated list of integers, where each integer represents a member's ID.

## **Output Format**

The first line of output displays the symmetric difference of the membership lists as a set.

The second line displays the sum of the elements in this symmetric difference.

Refer to the sample output for the formatting specifications.

## Sample Test Case

```
Input: 3
1 2 3
2 3 4
5 6 7
Output: {1, 4, 5, 6, 7}
23

Answer

# You are using Python
k = int(input())
result = set()

for _ in range(k):
    current_set = set(map(int, input().split()))
    result = result ^ current_set # symmetric difference

# Format output as sorted set with commas and spaces
```

formatted\_result = '{' + ', '.join(str(x) for x in sorted(result)) + '}'
print(formatted\_result)
print(sum(result))
